UBER

DATA ANALYTICS DASHBOARD

A Power BI business analytics project exploring ride bookings, revenue, vehicle performance, cancellations, and customer experience.

PROJECT TYPE	TOOL / PLATFORM	PERIOD
Data Analytics	Microsoft Power BI	2024 (as described in project notes)

1. Project Overview

The Uber Data Analytics Dashboard is designed to review ride-sharing business performance using interactive visualizations. It brings together booking patterns, vehicle performance, revenue, cancellation trends, ride distances, and rating information to help identify operational strengths and areas for improvement.

Project objectives

• Monitor booking volume and booking outcomes over time.

• Compare vehicle categories using bookings and distance travelled.

• Review revenue contribution by payment method and identify high-value customers.

• Understand the main reasons for customer and driver cancellations.

• Compare customer and driver ratings across vehicle types.

2. Key Metrics Summary

Metric	Value stated in project notes
Total bookings	148.77K
Success rate	65.96% (93K completed rides)
Cancellation rate	25% (37.43K cancelled bookings)
Customer cancellations	19.15% (27K)
Driver cancellations	7.45% (10.5K)

Note: These figures are reproduced from the supplied project README. Some figures in the README use different totals in different sections; they are presented as reported rather than reconciled.

3. Dashboard Sections and Visualizations

Overall Performance

A time-series chart tracks ride volume and helps identify demand fluctuations. A pie or doughnut chart summarizes booking statuses such as completed and cancelled bookings.

Vehicle Type Analysis

A table or bar chart compares vehicle categories by bookings and distance. The project notes identify Auto as the leading category by total bookings in the listed fleet analysis.

Revenue Analytics

A stacked bar chart compares revenue by payment method. A leaderboard highlights the top five customers by total booking value, while a histogram shows daily ride-distance distribution.

Cancellation Intelligence

Separate pie charts summarize reasons for customer-initiated and driver-initiated cancellations, helping reveal process issues that may be addressed.

Rating and Quality Assessment

Card visuals compare customer and driver ratings by vehicle type, supporting a quick view of service quality and satisfaction.

4. Vehicle Fleet Analysis

Vehicle type	Total bookings	Successful bookings	Average distance	Total distance
Go Mini	10.34M	9.41M	25.99 km	482K km
Go Sedan	9.37M	8.54M	25.98 km	433K km
Auto	12.88M	11.73M	25.99 km	602K km
eBike/Bike	11.46M	10.44M	26.11 km	537K km
UberXL	1.53M	1.41M	25.72 km	72K km
Premier Sedan	6.28M	5.73M	25.95 km	292K km

As reported in the supplied notes, Auto has the highest total bookings and total distance among the vehicle categories shown. Average distances are close to 26 km across categories.

5. Revenue and Payment Insights

• UPI is identified in the project notes as the largest revenue contributor (approximately 2.0M).

• Cash is identified as the second-highest contributor (approximately 1.1M).

• Uber Wallet, credit card, and debit card are reported as lower contributors.

• The dashboard also includes a top-five-customer view based on total booking value.

6. Cancellation Analysis

Customer cancellation reasons listed in the project notes:

Reason	Share	Count
Wrong address	22.50%	2.36K
Change of plans	21.86%	2.30K
Driver issues	22.41%	2.35K
Driver not moving	22.24%	2.34K
App issues	11.00%	1.16K

Driver cancellation reasons are grouped in the project notes into customer-related issues, customer behavior, personal and car issues, and capacity issues, each reported at approximately one-quarter of the listed total.

7. Ratings and Customer Experience

• Customer ratings are reported in a narrow range of 4.40–4.41 across vehicle types; Go Sedan is listed at 4.41.

• Driver ratings are reported in a range of 4.23–4.24; UberXL is listed at 4.24.

• The notes suggest customer ratings are slightly higher than driver ratings, so driver experience may merit further investigation.

8. Data Fields Used

• Date and Time

• Booking ID and Booking Status

• Customer ID and Vehicle Type

• Pickup Location and Drop Location

• Average VTAT and Average CTAT

• Customer cancellations and customer cancellation reason

• Driver cancellations and driver cancellation reason

• Incomplete rides and incomplete ride reason

• Booking Value and Ride Distance

• Driver Ratings and Customer Rating

• Payment Method

9. Key Business Insights

Strengths

• Customer satisfaction ratings are consistently high in the project notes.

• The dashboard covers multiple vehicle categories and different travel needs.

• UPI is reported as the strongest payment channel.

• Daily distance coverage is described as relatively consistent, around 6K–8K km.

Areas for improvement

• Investigate the reported 25% cancellation rate and prioritize preventable causes.

• Review driver experience because driver ratings are slightly lower than customer ratings.

• Plan for seasonal demand changes, including the reported dip in February and stronger July–August period.

• Use the top-customer view to develop appropriate retention strategies.

10. Conclusion

This project demonstrates how Power BI can turn ride-booking data into a business performance dashboard. The combination of trend charts, payment comparisons, vehicle analysis, cancellation breakdowns, and ratings supports data-informed decisions. The main opportunities highlighted by the project notes are reducing cancellations, improving driver experience, and responding to changes in ride demand.

Prepared from the user-provided Uber project cover image and project README. Metrics and labels follow the supplied project notes; the report does not independently validate the underlying Power BI model.
